# (Discrete) Dislocation Dynamics Simulations

Mesoscopic simulations of dislocations collective properties  
and plastic deformation

### Mechanical properties

# Simulations of plastic deformation

## Atomistic modeling

nm and  $10^{-15}$  s

## DD and Phase field

$\mu\text{m}$  and  $10^{-10} - 10^{-5}$  s

## FEM, BEM, etc..

mm - km and s - y

Modeling in 'material sciences' and 'mechanical engineering' is today a strategic activity of many businesses.

# Atomistic simulations of plasticity

Atomistic simulations can today accounts for more than  $10^{10}$  atoms.

Nevertheless such simulations will always be restricted to the modeling of volumes as small as a few nanometers per side.

# DD simulations

At beginning - 2D simulations

- **Line tension, obstacle pinning**  
but planar slip in a single plane

- **Patterning:  $(1/r)$  interactions**  
but no curvature and line tension

**Real plasticity is a combination of both**

---

# Three dimensions DD simulations

3D DD - microMegas (1992)

Elastic Properties

Local rules

Periodic boundary conditions ...

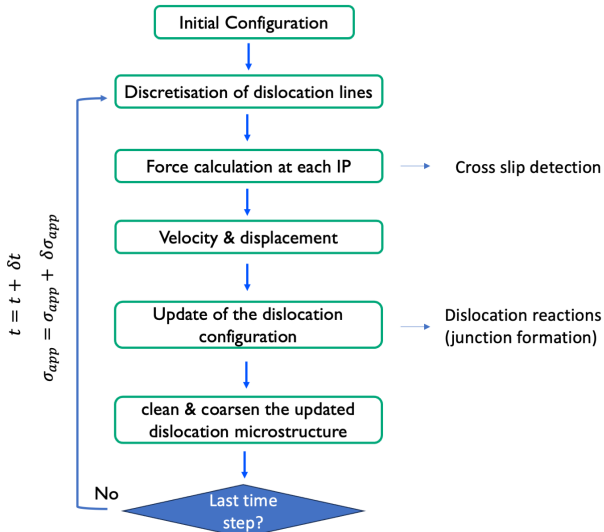

---

# What are DD simulations good for?

- Expand the dislocation theory predictions
  - To Explain and to model complex plastic behaviors
  - To simulate single crystal, polycrystals and multiphased materials with a unique formalism.
- Do the link between discrete and continuous modeling
  - Identify, test and validate new physically justified material laws.
  - Measure model parameters for large scale simulations (coarse graining).

- 
- 1 Introduction
  - 2 Discrete Dislocation Dynamics Simulations (DD)
  - 3 Main ingredients in DD simulations**
  - 4 DD : Boundary conditions
  - 5 Simple examples

# DD flowchart

# Discretization of the dislocation lines

## Lattice simulations

Dislocation lines are describe with "chains" of straight segments including one or few integration points (IP) to compute forces.

- Crystal symmetry
- Coding simplicity

# Remarks on line discretization

- The number of integration point is imposed by the stress gradient

# Dislocation cross-slip

Cross-slip, like other stochastic processes taking place during dislocation dynamics can be simulated with a "Monte-Carlo" algorithm, if one can define the corresponding probability function.

$$P(l) = \beta \frac{l}{l_0} \frac{\Delta t}{\Delta t_0} \exp\left(\frac{|\tau| - \tau_{III}}{kT}\right)$$

# Forces in infinite crystals

- Dislocation segment stress field,  $\sigma_i$ .
- Peach-Koehler force

$$\frac{\mathbf{F}_j}{L_j} = \left( \sum_i \sigma_i + \sigma_{app} \right) \cdot \mathbf{b}_j \times \boldsymbol{\ell}_j$$

- Line tension correction

$$\Gamma \approx \frac{\mu b^2}{4\pi R} \ln\left(\frac{R}{r_0}\right)$$

Computation of forces at the IP is the most CPU extensive part of DD simulations ( $\approx 90\%$ ).

## Dynamics and time integration

For many problems, dislocations can be considered as classical objects with a very low mass and high energy. Hence, Newton law equations can be integrated without considering inertial effects.

$$\mathbf{r}(t + \delta t) = \mathbf{r}(t) + \delta t \cdot \mathbf{v}(t)$$

$$\mathbf{v}(t) = \frac{\boldsymbol{\tau}^*(t) \cdot \mathbf{b}}{B(T)}$$

$B$  is a viscous coefficient accounting mainly for dislocation-phonon interactions. It is material and temperature dependent.

# Optimizations of the forces computation

- ❶ Multi-poles algorithm
  - ❷ Parallelization
  - ❸ Multi time steps integrations
- Today, free (and open source) codes exist and can be download on the web.

    - etc ...

## Deformation and rotation fields

A plastic shear increment on glide system “s” is induced by each displacement of the dislocations in their glide planes.

$$\gamma^{(s)} = \sum_{i=1}^N \frac{|b_i| A_i^{(s)}}{V}$$

At each time step, increments of the deformation and the rotation tensor are calculated for the total simulated volume (or in sub-volumes)

$$d\epsilon_{ij}^p = \sum_{s=1}^n \gamma^{(s)} d\epsilon^{(s)} \quad \text{et} \quad d\Omega_{ij}^p = \sum_{s=1}^n \gamma^{(s)} d\omega^{(s)}$$

with

$$d\epsilon^{(s)} = \frac{1}{2}(\mathbf{m}^{(s)} \otimes \mathbf{n}^{(s)} + \mathbf{n}^{(s)} \otimes \mathbf{m}^{(s)})$$
$$d\omega^{(s)} = \frac{1}{2}(\mathbf{m}^{(s)} \otimes \mathbf{n}^{(s)} - \mathbf{n}^{(s)} \otimes \mathbf{m}^{(s)})$$

m=shear direction

n=glide plane normal

# Dislocation-dislocation reactions

## Dipole

## Junctions

## Coplaire

## Colinéaire

- Contact reactions are elastically driven (poorly affected by dislocation core).
- Additional degree of freedom are introduced along the lines at contact points.
- Junction zipping and unzipping is controlled by line tensions at the triple nodes.

# Comparison with atomistic simulations

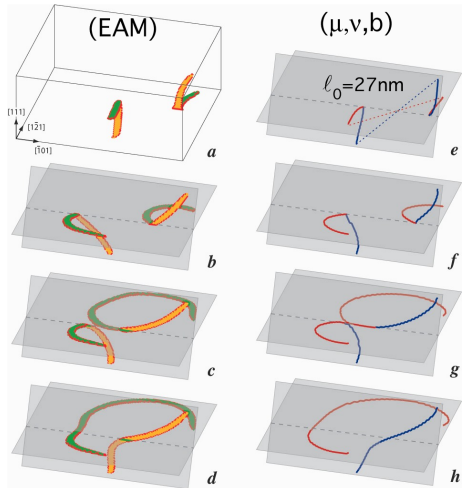

## Collinear annihilation

Comparison between MD and DD (here AI).

At critical curvature (b et f):

$$\text{MD } \tau_c/\mu = 1.85 \cdot 10^{-2}$$

$$\text{DD } \tau_c/\mu = 1.67 \cdot 10^{-2}$$

- 1 Introduction
  - 2 Discrete Dislocation Dynamics Simulations (DD)
  - 3 Main ingredients in DD simulations
  - 4 DD : Boundary conditions**
  - 5 Simple examples

# Periodic boundary conditions (PBC)

## PBC

- Flux balance at boundaries
- Continuity of dislocation lines
- Infinite crystal mechanics

# Dislocation mean free path

PBC artifact: dislocation self annihilation

# Complex boundary conditions

## Surfaces and interfaces

Exemple : superalliajes

Confinement

Misfit

Multi-phases

# FEM and DD simulation coupling

Three solutions exist:

- 1 Superposition method  
(Vandergiesen:95):

$$\sigma_{dis} = \sigma_{dis inf} + \sigma_{CL}$$

- 2 Discrete-continuous model  
(Lemarchant:01):  
Here a DD simulation is used  
instead of the FEM  
constitutive plastic law.

# DD + FEM : Boundary value problem 1

## Superposition principle

1995 -> van der Giessen, Needleman et al. (2D)

-> 3D Fivel, Weygand

$$\sigma_{dis} = \sigma_{dis\infty} + \sigma_{bc}$$

The diagram illustrates the superposition principle for dislocation boundary value problems. It shows three domains:

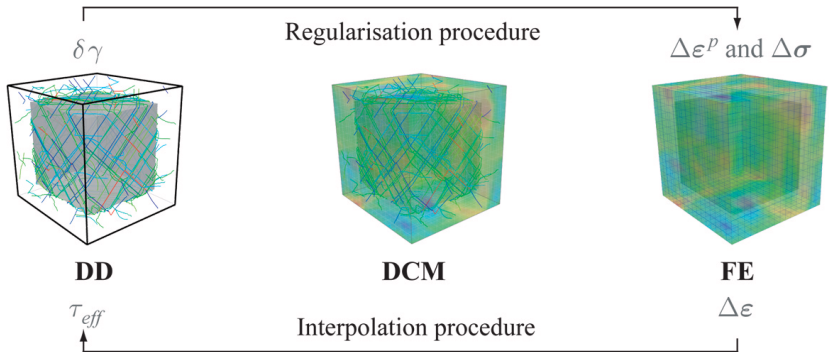

- Left Domain:** A domain with traction  $T_i^0$  on  $S_f$  and displacement  $u_i^0$  on  $S_u$ . The normal vector  $n_i$  is shown.
- Middle Domain (DD):** A domain with traction  $\tilde{T}_i$  on  $S_f$  and displacement  $\tilde{u}_i$  on  $S_u$ . A red box labeled  $\infty$  indicates a singularity.
- Right Domain (EF):** A domain with traction  $\hat{T}_i = T_i^0 - \tilde{T}_i$  on  $S_f$  and displacement  $\hat{u}_i = u_i^0 - \tilde{u}_i$  on  $S_u$ .

The equation  $\sigma_{dis} = \sigma_{dis\infty} + \sigma_{bc}$  is shown above the domains.

Dislocation singularities are moved to the surface  
Stresses must be interpolated in the volume
